ABSTRACT

---

 A method of using a first communications device, such as a mobile telephone, together with at least one other communications device, such as a telephone, comprises the steps of playing back audio signals in the first communications device, transmitting the same audio signals to the other communications device, and playing back the audio signals in the other communications device. By transmitting the audio signals played back in the first communications device to the other device and playing them back there, shared audio listening is achieved and in this way the communications devices can be used also for the shared listening to e.g. music. Thus it is possible for two persons present at different locations to listen to the same audio signals simultaneously or at least almost simultaneously.
